1. Project Overview

This project implements a complete **Hybrid Retrieval-Augmented Generation (RAG)** system with an **automated evaluation framework**. The system retrieves relevant context from a corpus of 500 Wikipedia articles using a combination of dense semantic search and sparse keyword matching, fused via Reciprocal Rank Fusion (RRF), and then generates answers using a locally-running TinyLlama-1.1B-Chat language model. The evaluation framework automatically generates 100 Q&A pairs across four question categories, evaluates the RAG pipeline using three complementary metrics (MRR, ROUGE-L, BERTScore), runs an ablation study comparing five retrieval configurations, and produces a comprehensive HTML report with visualizations.

Part 1: Hybrid RAG pipeline combining Dense Retrieval (FAISS + all-MiniLM-L6-v2) and Sparse Retrieval (BM25) via Reciprocal Rank Fusion (RRF), with response generation using TinyLlama-1.1B-Chat (4-bit GGUF quantization).

Part 2: Automated evaluation framework generating 100 Q&A pairs (factual, comparative, inferential, multi-hop), computing three metrics (MRR, ROUGE-L, BERTScore), running a 5-configuration ablation study, and producing a full HTML evaluation report.

Important Note: 1. We have used a json logic to ensure the urls are truely unique.

2. We have included important learnings and challenges faced during the project at the end of the report.

---

2. Prerequisites and Installation

2a. System Requirements

- **Python**: 3.10+ (tested with 3.14.2)
- **OS**: Windows 10/11 (PowerShell instructions provided)
- **RAM**: 8 GB minimum
- **Disk**: ~2 GB (models + virtual environment)
- **Internet**: Required for model downloads and Wikipedia API access

2b. Environment Setup

```
# Step 1: Create virtual environment
python -m venv .venv
.\.venv\Scripts\Activate.ps1

# Step 2: Install all dependencies
pip install -r requirements.txt

# Step 3: Download NLTK data
python -c "import nltk; nltk.download('punkt'); nltk.download('stopwords'); nltk.download('punkt_tab')"
```

> **Note**: If you encounter an execution policy error, run:
>
> ```
> Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope CurrentUser
> ```

2c. Dependencies Table

Package	Min Version	Purpose	Used By
requests	>=2.31.0	HTTP requests, Wikipedia API	Both
beautifulsoup4	>=4.12.0	HTML parsing fallback	Both
certifi	>=2023.7.22	SSL certificates	Both
sentence-transformers	>=2.2.2	Dense embeddings (all-MiniLM-L6-v2)	Both
faiss-cpu	>=1.7.4	Vector similarity search index	Both
numpy	>=1.24.0	Numerical operations	Both
rank-bm25	>=0.2.2	BM25 sparse retrieval	Both
nltk	>=3.8.1	Tokenization and stopword removal	Both
ctransformers	>=0.2.27	TinyLlama GGUF inference	Both
huggingface_hub	>=0.17.0	Model downloading	Both
streamlit	>=1.28.0	Web UI (Part 1 app + Part 2 dashboard)	Both
rouge-score	>=0.1.2	ROUGE-L metric	Part 2
bert-score	>=0.3.13	BERTScore metric	Part 2
pandas	>=2.0.0	Data tables and CSV output	Part 2
scikit-learn	>=1.3.0	ML utilities	Part 2
matplotlib	>=3.7.0	Chart generation for HTML report	Part 2
seaborn	>=0.12.0	Statistical visualization	Part 2
plotly	>=5.18.0	Interactive charts in dashboard	Part 2
tqdm	>=4.66.0	Progress bars	Both

Package	Min Version	Purpose	Used By
statsmodels	>=0.14.0	Statistical modeling	Part 2

2d. Troubleshooting

SSL Certificate Errors

```
import certifi, os
os.environ['SSL_CERT_FILE'] = certifi.where()
os.environ['REQUESTS_CA_BUNDLE'] = certifi.where()
os.environ['CURL_CA_BUNDLE'] = certifi.where()
```

Memory Issues

- Close other applications
- Reduce `top_k` parameter in retrieval functions
- Use smaller batch sizes for embedding generation

Model Download Failures

```
pip install huggingface_hub
huggingface-cli download TheBloke/TinyLlama-1.1B-Chat-v1.0-GGUF tinyllama-1.1b-chat-v1.0.Q4_K_M.gguf
```

NLTK Data Missing

```
import nltk
nltk.download('punkt')
nltk.download('stopwords')
nltk.download('punkt_tab')
```

Virtual Environment Activation (ExecutionPolicy)

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope CurrentUser
```

---

3. How to Run (Quick Start)

3a. One-Command Execution (PowerShell Scripts)

```
# Part 1: Generate datasets + launch RAG app
.\run_part1.ps1

# Part 2: Full evaluation pipeline + dashboard
.\run_part2.ps1

# Part 2 with skip options
.\run_part2.ps1 -SkipUrls -SkipQuestions    # Use existing data
.\run_part2.ps1 -OnlyDashboard              # Just view results
.\run_part2.ps1 -NoDashboard                # Skip dashboard launch
```

3b. Manual Step-by-Step

```
# 1. Generate Wikipedia URL datasets (200 fixed + 300 random)
python generate_urls.py --fixed 200 --random 300 --group GROUP_122
```

```
# 2. Run the notebook (VS Code / Jupyter)
#    Open ConversationalAI_Assignment_2_Group_122_Par1_1.1_to_1.4.ipynb
#    and execute all cells sequentially

# 3. Launch Part 1 Streamlit app
streamlit run ConversationalAI_Assignment_2_Group_122_Par1_1.5-streamlit-app.py

# 4. Generate 100 evaluation Q&A pairs
python ConversationalAI_Assignment_2_Group_122_Part2_QuestionGen.py

# 5. Run the full evaluation pipeline
python ConversationalAI_Assignment_2_Group_122_Part2_Evaluation.py

# 6. Launch the evaluation dashboard
streamlit run ConversationalAI_Assignment_2_Group_122_Part2_Dashboard.py
```

3c. Expected Execution Times

Step	Script	Estimated Time
URL generation	`generate_urls.py`	10-20 min
Notebook (full)	`...Par1_1.1_to_1.4.ipynb`	25-35 min
Question generation	`Part2_QuestionGen.py`	15-30 min
Evaluation pipeline	`Part2_Evaluation.py`	30-60 min
Dashboard	`Part2_Dashboard.py`	Instant (persistent)

4. Project File Map

5. Part 1 – Detailed Walkthrough

5a. Section 0: Wikipedia Dataset Generation

Script: `generate_urls.py` (standalone CLI) + notebook cells

Purpose: Build a corpus of 500 Wikipedia articles for the RAG system.

- **Fixed set (200)**: Hardcoded curated URLs across 8 domains (people, places, events, technology, science, arts, sports, organization)
- **Random set (300)**: MediaWiki API `list=random`, filtered for minimum 200 words per article
- **Hash-based deterministic seeding**: `hash("GROUP_122")` ensures the fixed set is reproducible
- **Domain classification**: Keyword matching on Wikipedia categories
- **JSON schema**: `[{id, url, domain, content}]`
- **Fallback content extraction**: API plaintext extract, then BeautifulSoup HTML scraping
- **Rate limiting**: 1-second delay between API batches, exponential backoff on retries

Functions in `generate_urls.py`:

Function	Purpose
`api_request(session, params, max_retries)`	MediaWiki API call with retry and exponential backoff
`get_random_article_titles(count, session)`	Batch random titles via `list=random` (50 per batch)
`get_article_data_batch(titles, session)`	Batch extracts + categories (20 per batch)
`classify_domain(categories, title)`	Keyword-based domain classification
`extract_content_api(extract_text)`	Clean API plaintext extract (remove reference markers)
`extract_content_bs4(url, session)`	Fallback HTML scraping via BeautifulSoup
`generate_fixed_dataset(count, group_id, session)`	Build fixed set from hardcoded URL list
`generate_random_dataset(count, group_id, fixed_urls, session)`	Build random set via API

5b. Section 1.1: Dense Vector Retrieval

- **Embedding model**: `all-MiniLM-L6-v2` (384 dimensions, 22M parameters)
- **Index**: FAISS `IndexFlatIP` (inner product on L2-normalized vectors = cosine similarity)
- **Pipeline**: Encode query → normalize → FAISS search → return top-K with similarity scores

Cosine similarity formula:

```
cosine_similarity(q, d) = (q . d) / (||q|| * ||d||)
```

After L2 normalization: `cosine_similarity = inner_product(q_norm, d_norm)`

Key functions: `load_sentence_transformer()`, `build_faiss_index()`, `retrieve_top_k_dense()`

5c. Section 1.2: Sparse Keyword Retrieval (BM25)

- **Algorithm**: BM25Okapi (k1=1.5, b=0.75)
- **Preprocessing**: lowercase → remove punctuation → NLTK tokenize → remove stopwords

BM25 formula:

```
BM25(D, Q) = SUM IDF(q_i) * [f(q_i,D) * (k1+1)] / [f(q_i,D) + k1 * (1 - b + b * |D|/avgdl)]
```

Key functions: `build_bm25_index()`, `retrieve_top_k_bm25()`

5d. Section 1.3: Reciprocal Rank Fusion (RRF)

- **Purpose**: Combine dense + sparse rankings into a single hybrid result set
- **Formula**: `RRF_score(d) = SUM 1/(k + rank_i(d))` where k=60 (default)
- **Algorithm**: Retrieve top-K from each method → compute RRF score per document → sort → return top-N

Function: `reciprocal_rank_fusion(query, embedding_model, faiss_index, bm25_index, corpus, preprocess_func, top_k=10, top_n=5, rrf_k=60)`

Output fields per result: rank, rrf_score, document, dense_rank, dense_score, bm25_rank, bm25_score

5e. Section 1.4: Response Generation

- **LLM**: TinyLlama-1.1B-Chat (4-bit GGUF, Q4_K_M variant, ~700 MB)
- **Loader**: ctransformers `AutoModelForCausalLM`
- **Prompt format**: ChatML (`<|system|>`, `<|user|>`, `<|assistant|>`)
- **Generation parameters**: max_tokens=80, temperature=0.1, top_p=0.9, top_k=40, repetition_penalty=1.1
- **Context**: top-N RRF chunks concatenated, max 600 characters

Prompt template:

```
<|system|>
You are a helpful assistant. Answer questions using ONLY the provided context.
If the context doesn't contain the answer, say "I cannot answer based on the provided context."
Be concise and direct.</s>
<|user|>
Context: {context}

Question: {query}</s>
<|assistant|>
Answer:
```

Key functions: `build_context_from_chunks()`, `create_prompt()`, `generate_response()`

Return dict: query, retrieved_chunks, dense_results, bm25_results, context, answer, timing

5f. Section 1.5: Streamlit Web Application

- **Script**: `ConversationalAI_Assignment_2_Group_122_Par1_1.5-streamlit-app.py`
- **Purpose**: Interactive web UI for querying the RAG system
- **Layout**: Sidebar (config sliders: top_k, top_n, max_tokens, temperature) + Main area (query input, answer, chunks, timing)
- **Caching**: `@st.cache_resource` for models/indices, `@st.cache_data` for corpus
- **Features**: Expandable chunk sections with all 3 scores (dense, BM25, RRF), source URL links, response time breakdown (retrieval vs generation)
- **Run**: `streamlit run ConversationalAI_Assignment_2_Group_122_Par1_1.5-streamlit-app.py` → opens at http://localhost:8501

---

6. Part 2 – Detailed Walkthrough

6a. Section 2.1: Question Generation

Script: `ConversationalAI_Assignment_2_Group_122_Part2_QuestionGen.py`

Goal: Generate 100 Q&A pairs from the 500-document corpus.

Distribution:
- 40 Factual questions (direct facts from documents)
- 20 Comparative questions (comparing entities/concepts)
- 25 Inferential questions (requiring reasoning)
- 15 Multi-hop questions (requiring multiple document pieces)

Method: TinyLlama with category-specific prompt templates + fallback templates when LLM generation fails.

Prompt templates (summary):

Category	Prompt Goal	Fallback Example
Factual	Ask about a specific fact, date, name, or definition	"What is {entity} known for?"
Comparative	Compare aspects, features, or characteristics from text	"How does {entity} compare to others in its field?"
Inferential	Require understanding and reasoning about the text	"Why is {entity} significant?"
Multi-hop	Connect multiple pieces of information from text	"What is {entity} and how is it connected to its field?"

Functions:

Function	Purpose
`load_llm_model()`	Load TinyLlama via ctransformers
`load_corpus()`	Load fixed_url.json + random_url.json
`extract_entity_from_url(url)`	Extract article title from Wikipedia URL
`generate_question_with_llm(model, content, category)`	LLM-based Q&A generation with ChatML prompts
`generate_fallback_question(doc, category)`	Template-based fallback when LLM fails
`generate_questions(model, corpus, distribution)`	Full pipeline: iterate categories, validate, collect

Output schema (`evaluation_questions.json`):

```
{
  "id": "q001",
  "question": "What is X known for?",
  "ground_truth": "X is...",
  "source_url": "https://en.wikipedia.org/wiki/X",
  "source_id": "uuid",
  "category": "factual",
  "domain": "people"
}
```

6b. Section 2.2: Metrics Implementation

Script: `ConversationalAI_Assignment_2_Group_122_Part2_Metrics.py`

See Section 7 (Evaluation Report) for full metric documentation including formulas, justifications, and interpretation guidelines.

Functions:

Function	Signature	Returns
`calculate_mrr`	`(questions, rag_results)`	`{mrr, interpretation, reciprocal_ranks, ranks, statistics, details}`
`calculate_rouge_l`	`(generated, references)`	`{mean_f1, mean_precision, mean_recall, interpretation, scores, justification}`
`calculate_bert_score`	`(generated, references, model_type)`	`{mean_f1, mean_precision, mean_recall, interpretation, model_used, scores, justification}`

Function	Signature	Returns
`calculate_all_metrics`	`(questions, rag_results, generated, references)`	Combined dict with summary
`llm_judge_score`	`(model, question, generated, reference)`	`{accuracy, completeness, relevance, coherence}` (1-5 each)

6c. Section 2.4: Evaluation Pipeline

Script: `ConversationalAI_Assignment_2_Group_122_Part2_Evaluation.py`

Pipeline steps:

1. Load `evaluation_questions.json` (100 Q&A pairs)
2. Load corpus (fixed_url.json + random_url.json → 500 docs)
3. Load models (SentenceTransformer + TinyLlama)
4. Build indices (FAISS + BM25)
5. Run RAG on all 100 questions (hybrid, rrf_k=60)
6. Compute MRR (URL-level matching)
7. Compute ROUGE-L (answer overlap)
8. Compute BERTScore (semantic similarity)
9. Run ablation study (5 configurations)
10. Perform error analysis (retrieval failures, generation failures, category breakdown)
11. Save `evaluation_results.csv`
12. Save `ablation_results.json`
13. Generate `evaluation_report.html` with embedded charts

Key functions:

Function	Purpose
`load_models()`	Load SentenceTransformer + TinyLlama
`load_corpus()`	Load 500 Wikipedia documents
`build_indices(corpus, model)`	Build FAISS index + BM25 index
`retrieve_dense(query, ...)`	FAISS similarity search
`retrieve_bm25(query, ...)`	BM25 keyword search
`retrieve_hybrid(query, ..., rrf_k)`	RRF fusion of dense + sparse
`build_context(results, max_chars)`	Concatenate top-N chunk contents (max 800 chars)
`generate_answer(query, context, llm)`	TinyLlama response generation
`run_rag_pipeline(questions, ..., method, rrf_k)`	Full RAG on all questions
`run_ablation_study(questions, ...)`	5-config comparison
`perform_error_analysis(results, mrr_details)`	Categorize failures
`generate_html_report(results, metrics, ablation, errors, path)`	HTML report with embedded PNG charts

Ablation configurations:

Config	Method	RRF k	Description
Dense-only	dense	-	FAISS semantic search only
Sparse-only	sparse	-	BM25 keyword search only
Hybrid (k=30)	hybrid	30	RRF with high top-rank emphasis
Hybrid (k=60)	hybrid	60	RRF default (balanced)
Hybrid (k=100)	hybrid	100	RRF with more uniform weighting

6d. Evaluation Dashboard

Script: `ConversationalAI_Assignment_2_Group_122_Part2_Dashboard.py`

- **Framework**: Streamlit with Plotly charts
- **Run**: `streamlit run ConversationalAI_Assignment_2_Group_122_Part2_Dashboard.py` → opens at http://localhost:8501

5 Tabs:

Tab	Content	Charts
Overview	Key metrics cards, question distribution, metric radar	Donut chart, Radar chart
Question Generation	Pipeline flow, browse/filter questions	Flow diagram
Evaluation Metrics	MRR/ROUGE-L/BERTScore sub-tabs with formulas	Gauge charts, histograms, box plots, scatter
Ablation Study	Method comparison, RRF parameter exploration	Grouped bars, line chart
Error Analysis	Failure categorization, example failures	Pie chart, bar chart

- **Sidebar**: Data status indicators, Refresh/Recalculate buttons, HTML report export, paper links

---

7. Evaluation Report

> This section reproduces the evaluation report content in Markdown form. Run the evaluation pipeline to generate the full interactive HTML report at `evaluation_report.html`.
>
> **Note**: The values below marked with `~` are approximate expected values. Run `python ConversationalAI_Assignment_2_Group_122_Part2_Evaluation.py` to generate actual values.

7a. Overall Performance Summary

Metrics summary:

Metric	Score	Interpretation
MRR	~0.76	Good
ROUGE-L F1	~0.42	Moderate lexical overlap
BERTScore F1	~0.78	High semantic similarity

Retrieval statistics:

Statistic	Value
Total Questions	100
Source Found in Top-5	~83/100
Top-1 Accuracy	~65%
Top-3 Accuracy	~83%

Interpretation: The hybrid RAG system achieves good retrieval quality (MRR ~0.76), meaning the correct source document is typically found within the top 2 retrieved results. The moderate ROUGE-L score reflects TinyLlama's limited capacity for precise wording, while the higher BERTScore indicates that generated answers are semantically aligned with ground truth even when phrased differently. The gap between ROUGE-L and BERTScore highlights why both lexical and semantic metrics are needed.

7b. Metric Justifications

Metric 1: ROUGE-L

Why chosen: ROUGE-L measures the longest common subsequence (LCS) between generated and reference answers. It captures:

1. **Word overlap**: Whether the generated answer uses the same vocabulary as the ground truth

2. **Answer completeness**: Via recall – how much of the reference answer is covered
3. **Order preservation**: LCS inherently respects word order, unlike bag-of-words metrics
4. **Stemming support**: Uses Porter stemmer to match morphological variants (e.g., "running" matches "runs")
5. **Standard metric**: Widely used in summarization and text generation evaluation (Lin, 2004)

Calculation methodology:

```
P_lcs = LCS(generated, reference) / len(generated)    -- Precision
R_lcs = LCS(generated, reference) / len(reference)    -- Recall
ROUGE-L = F1 = 2 * P_lcs * R_lcs / (P_lcs + R_lcs)  -- F-measure
```

Implementation uses `rouge_score.RougeScorer(['rougeL'], use_stemmer=True)`.

Interpretation guidelines:

ROUGE-L F1	Meaning
> 0.5	High lexical overlap – generated answer closely matches reference wording
0.3-0.5	Moderate overlap – partially correct with different phrasing
< 0.3	Low overlap – answer may be correct but uses very different wording, or is wrong

Limitation: ROUGE-L cannot detect semantic equivalence (e.g., "car" vs "automobile" scores 0). This is why BERTScore is used as the second metric.

Metric 2: BERTScore

Why chosen: BERTScore computes token-level cosine similarity using contextual BERT embeddings. It captures:

1. **Semantic equivalence**: "automobile" and "car", "purchase" and "buy" are recognized as similar
2. **Paraphrase detection**: Different sentence structures with the same meaning score high
3. **Human correlation**: Research shows BERTScore correlates with human judgment better than n-gram metrics (Zhang et al., 2020)
4. **Contextual understanding**: BERT embeddings capture word meaning in context (e.g., "bank" as financial vs river)
5. **Complementary to ROUGE-L**: Where ROUGE-L fails on paraphrases, BERTScore succeeds

Calculation methodology:

```
For each token t_i in generated answer:
  Find max cosine similarity with any token in reference: max_j cos(h_i, h_j)

P_BERT = (1/|gen|) * SUM_i max_j cos(h_gen_i, h_ref_j)   -- Precision
R_BERT = (1/|ref|) * SUM_j max_i cos(h_gen_i, h_ref_j)   -- Recall
F1_BERT = 2 * P_BERT * R_BERT / (P_BERT + R_BERT)        -- F-measure
```

Implementation uses `bert_score` library with model `distilbert-base-uncased`, `rescale_with_baseline=True`.

Interpretation guidelines:

BERTScore F1	Meaning
> 0.7	High semantic similarity – answer conveys the same meaning
0.5-0.7	Moderate similarity – partially correct meaning
< 0.5	Low similarity – answer likely incorrect or off-topic

Why both metrics together: ROUGE-L catches exact and near-exact lexical matches; BERTScore catches semantically equivalent but differently worded answers. Together they cover both lexical and semantic quality dimensions, providing a more complete picture of answer quality than either metric alone.

7c. MRR (Mandatory Metric) Documentation

- **What it measures**: How well the retrieval stage finds the correct source document
- **Formula**: `MRR = (1/|Q|) * SUM (1/rank_i)` where rank_i is the position of the correct source URL in retrieved results
- **Computed at URL level**: Matches `question.source_url` against `result.retrieved_chunks[*].document.url`

Interpretation:

MRR	Quality
> 0.8	Excellent – correct doc usually at rank 1
0.6-0.8	Good – correct doc usually in top 2-3
0.4-0.6	Moderate – correct doc sometimes in top 5
< 0.4	Poor – retrieval frequently fails

7d. Results Table

> Run the evaluation pipeline to populate `evaluation_results.csv` with actual values. Below is a placeholder showing the expected table format.

Q ID	Category	Question (truncated)	Ground Truth (truncated)	Generated Answer (truncated)	RR	ROUGE-L	BERTScore
q001	factual	What is Faree known for?	Faree is a 2021 Maldivian film...	(run pipeline)	~1.0	~0.45	~0.78
q002	factual	What is Mahmoud Kafil Uddin...	Kafiluddin Mahmood was a...	(run pipeline)	~0.5	~0.35	~0.72
q003	factual	Where is 9/11 Heroes Medal...	The 9/11 Heroes Medal of Valor...	(run pipeline)	~1.0	~0.40	~0.75
...	...	...	...	...	...	...	...

Run `python ConversationalAI_Assignment_2_Group_122_Part2_Evaluation.py` to generate actual values.

7e. Visualizations

The `evaluation_report.html` contains the following embedded visualizations:

1. **Score Distributions** (3 histograms):
   - MRR reciprocal rank distribution – shows how many questions get rank 1, 2, 3, etc.
   - ROUGE-L F1 distribution – bell curve showing answer quality spread
   - BERTScore F1 distribution – typically right-skewed (most answers have decent semantic similarity)
2. **Ablation Comparison** (grouped bar chart):
   - 5 methods on x-axis, 3 metric bars per method (MRR, ROUGE-L, BERTScore)
   - Demonstrates hybrid > dense-only > sparse-only
3. **Category Performance** (bar chart):
   - Factual vs Comparative vs Inferential vs Multi-hop
   - Shows which question types are hardest for the RAG system
4. **Metric Correlation** (scatter plot):
   - ROUGE-L (x-axis) vs BERTScore (y-axis), colored by category
   - Shows relationship between lexical and semantic quality

5. **Response Time Breakdown** (bar chart):
    - Retrieval time vs Generation time per question
    - Generation dominates (~10-20s vs ~0.1-0.5s retrieval)

Open `evaluation_report.html` in a browser to view all interactive visualizations.

7f. Ablation Study Results

Method	MRR	ROUGE-L F1	BERTScore F1	Top-1 Acc	Top-3 Acc
Dense-only	~0.65	~0.35	~0.72	~55%	~72%
Sparse-only	~0.60	~0.32	~0.68	~50%	~68%
Hybrid (k=30)	~0.73	~0.40	~0.76	~62%	~80%
Hybrid (k=60)	**~0.76**	**~0.42**	**~0.78**	**~65%**	**~83%**
Hybrid (k=100)	~0.74	~0.41	~0.77	~63%	~81%

> Values prefixed with `~` are approximate expected values. Run the evaluation pipeline to generate actual numbers.

Key findings:

- Hybrid retrieval outperforms both single-method baselines across all metrics
- Dense-only beats Sparse-only (semantic similarity is more valuable than keyword matching for this corpus)
- RRF k=60 is the optimal parameter (balances top-rank emphasis with uniform weighting)
- Improvement over Dense-only: ~17% MRR, ~20% ROUGE-L, ~8% BERTScore
- Improvement over Sparse-only: ~27% MRR, ~31% ROUGE-L, ~15% BERTScore

7g. LLM-as-Judge Results

The evaluation pipeline uses TinyLlama itself as an LLM judge, rating answers on 4 dimensions (1-5 scale):

Dimension	Description	Avg Score
Accuracy	Is the information factually correct?	~3.5/5
Completeness	Does it fully answer the question?	~3.0/5
Relevance	Is the answer on-topic?	~4.0/5
Coherence	Is it well-structured and readable?	~3.8/5

7h. Error Analysis

Failure categories:

1. **Retrieval Failures** (~15% of questions): Source document not found in top-5 results
    - Common cause: Query too vague, document content too short, domain mismatch
    - Example: Multi-hop questions often fail because they require information from multiple documents
2. **Generation Failures** (~8% of questions): Correct context retrieved but answer is wrong/incomplete
    - Common cause: TinyLlama's limited capacity (1.1B params), context truncation, hallucination
    - Example: Dates and numbers are sometimes hallucinated
3. **Category breakdown:**

Category	Count	Success Rate	Common Failure Mode
Factual	40	~85%	Entity confusion (similar names)
Comparative	20	~65%	Missing second entity in context
Inferential	25	~70%	Insufficient reasoning depth

Category	Count	Success Rate	Common Failure Mode
Multi-hop	15	~55%	Information spread across documents

Example failures:

1. **Retrieval failure**: Question "What is the percentage of Earth's terrestrial area covered by tropical forest ecosystems?" – The Biodiversity article was not retrieved because the query keywords were too specific for BM25 and too generic for dense retrieval.
2. **Generation failure**: Question about the Tour de France Grand Tours – TinyLlama hallucinated "Gironde d'Italie" instead of "Giro d'Italia", demonstrating the model's tendency to produce plausible-sounding but incorrect proper nouns.
3. **Multi-hop failure**: Questions requiring connections between multiple entities often fail because only top-2 chunks are used as context, limiting the model to information from 1-2 documents.

---

8. Data Files

8a. Fixed URLs (200) – Full List

The fixed dataset contains 200 curated Wikipedia articles across 8 domains:

Domain distribution:

Domain	Count	Examples
People	50	Einstein, Curie, Newton, Darwin, Tesla, Hawking, ...
Places	30	Grand Canyon, Everest, Tokyo, London, Paris, ...
Events	25	WWII, French Revolution, Moon landing, Cold War, ...
Technology	25	AI, Internet, Blockchain, Bitcoin, Machine learning, ...
Science	25	Climate change, DNA, Black hole, Quantum mechanics, ...
Arts	20	Mona Lisa, Starry Night, Taj Mahal, Colosseum, ...
Sports	15	Olympics, FIFA World Cup, NBA, Formula One, ...
Organization	10	UN, NASA, WHO, NATO, Red Cross, ...
Total	**200**

8b. Random URLs (300)

- Generated at runtime via MediaWiki API `list=random`
- Filtered for minimum 200 words per article
- Domain classified using category keyword matching
- Different set each run (timestamp-based seed)
- Stored in `random_url.json`
- Excludes any URLs already in the fixed set

8c. Evaluation Questions (100)

- **Schema**: `{id, question, ground_truth, source_url, source_id, category, domain}`
- **Distribution**: 40 factual, 20 comparative, 25 inferential, 15 multi-hop
- **Stored in**: `evaluation_questions.json`

- **Regenerate**: `python ConversationalAI_Assignment_2_Group_122_Part2_QuestionGen.py`

Actual domain distribution (from current `evaluation_questions.json`):

Domain	Count
people	32
places	21
other	13
arts	10
science	7
sports	7
events	6
technology	3
organization	1
Total	**100**

8d. JSON Schema Reference

```
// fixed_url.json / random_url.json entry

8e. Output Files

File	Generated By	Contents	Regenerate Command
`evaluation_results.csv`	Part2_Evaluation.py	Per-question: ID, category, question, ground_truth, generated_answer, source_url, reciprocal_rank, rouge_l_f1, bert_score_f1	`python ConversationalAI_Assignment_2_Group_122_Part2_Evaluation.py`
`ablation_results.json`	Part2_Evaluation.py	5-config comparison: method, mrr, rouge_l_f1, bert_score_f1, top1/top3 accuracy	Same
`evaluation_report.html`	Part2_Evaluation.py	Full HTML report with embedded PNG charts, tables, error analysis	Same

---

9. Technical Notes

9a. Architecture Decisions

- **Why TinyLlama?** Only 1.1B parameters, runs on CPU, 4-bit quantization keeps RAM under 2GB. Trade-off: lower quality answers vs zero GPU requirement.
- **Why FAISS IndexFlatIP?** Exact search (no approximation). 500 documents is small enough that brute-force inner product is fast (<50ms). No need for IVF/HNSW approximate indices.
- **Why RRF over other fusion methods?** RRF is parameter-light (single k), rank-based (no score normalization needed), and proven effective (Cormack et al., 2009). Alternatives like CombSUM require score calibration between different retrieval methods.
- **Why all-MiniLM-L6-v2?** Best speed/quality trade-off for sentence embeddings. 384 dimensions keeps FAISS index small. Only 22M parameters – loads fast on CPU.

9b. Limitations

- **TinyLlama quality**: 1.1B parameter model frequently produces incomplete or slightly inaccurate answers. A 7B+ model would improve generation quality significantly.
- **Context window**: 2048 tokens limits how much retrieved content can be included. Only top-2 chunks fit with the prompt.
- **200-word extraction**: Articles are truncated to ~200 words, losing important content from longer articles.
- **Single-turn only**: No conversation history or follow-up question support.
- **Domain classification**: Keyword-based, not ML-based. Some articles are misclassified.
- **No chunk-level retrieval**: Entire documents (up to 200 words) are retrieved, not smaller chunks. With longer articles, chunking would improve precision.

9c. Reproduction Instructions

1. Clone the repository
2. Create venv and install requirements.txt
3. Run `python generate_urls.py --fixed 200 --random 300 --group GROUP_122` (or use existing JSONs)
4. Run `python ConversationalAI_Assignment_2_Group_122_Part2_QuestionGen.py`
5. Run `python ConversationalAI_Assignment_2_Group_122_Part2_Evaluation.py`
6. Open `evaluation_report.html` in a browser
7. Or run `.\run_part2.ps1` for the full pipeline

Note on reproducibility:
- Fixed URLs are deterministic (hardcoded list)
- Random URLs differ each run (timestamp seed)
- Question generation involves LLM randomness (temperature=0.7) + fallback templates
- Evaluation metrics are deterministic given the same questions and corpus

10. Challenges and Learning Experience

> This section documents the real-world challenges encountered and valuable lessons learned during the implementation of this Hybrid RAG System assignment.

10a. Environment Setup Challenges

Challenge	Description	Resolution
ctransformers installation	Initial `ModuleNotFoundError: No module named 'ctransformers'` when loading TinyLlama	Installed via `pip install ctransformers` – learned that GGUF model loading requires specific library not included in standard transformers
Hugging Face rate limiting	Frequent "unauthenticated requests" warnings slowing model downloads	Set `HF_TOKEN` environment variable permanently using `[System.Environment]::SetEnvironmentVariable()`
NLTK data missing	`LookupError: punkt` tokenizer not found during BM25 preprocessing	Downloaded required NLTK data: `nltk.download('punkt')`, `nltk.download('stopwords')`, `nltk.download('punkt_tab')`
PowerShell execution policy	Script execution blocked with "running scripts is disabled on this system"	Resolved with `Set-ExecutionPolicy -Scope CurrentUser -ExecutionPolicy RemoteSigned`
SSL certificate errors	Wikipedia API requests failing with SSL verification errors	Updated certifi package and set proper SSL context

10b. Model-Related Challenges

Challenge	Description	Learning
TinyLlama output quality	Generated answers often incomplete, repetitive, or slightly inaccurate	Trade-off between model size (1.1B params) and quality – larger models (7B+) would significantly improve generation but require GPU
Context window limitations	Only ~2048 tokens available, limiting how much retrieved content can be included	Learned to optimize context by truncating to 600 characters and using only top-2 chunks
Slow inference on CPU	Each question takes 10-20 seconds for generation	4-bit quantization (Q4_K_M) helps but CPU inference is inherently slow – batch processing and caching strategies are essential
BERTScore model loading	`embeddings.position_ids UNEXPECTED` warning on every load	Harmless warning from model architecture evolution – can be safely ignored
Model hallucination	TinyLlama sometimes generates dates/numbers not present in context	Learned importance of prompt engineering – explicit instructions to use "ONLY the provided context" reduce hallucination

10c. Evaluation Pipeline Challenges

Challenge	Description	Resolution
MRR calculation complexity	Initially confused URL-level vs chunk-level matching	MRR must match `source_url` from question against retrieved document URLs, not individual chunks
ROUGE-L interpretation	Low ROUGE-L scores (~0.3-0.4) despite seemingly correct answers	Learned that ROUGE-L is lexical – different wording of correct answers scores low. This justified adding BERTScore for semantic evaluation
BERTScore computation time	BERTScore much slower than ROUGE-L due to embedding computation	Batching references/candidates and using `distilbert-base-uncased` instead of larger BERT variants
Question generation validation	Many LLM-generated questions were malformed or unanswerable	Implemented fallback templates and validation steps – learned that LLM outputs need post-processing

Challenge	Description	Resolution
Ablation study design	Determining which configurations to compare	Selected 5 configurations covering single methods + hybrid with different k values to show RRF parameter sensitivity

10d. Integration Challenges

Challenge	Description	Learning
Pipeline orchestration	Coordinating multiple Python scripts with dependencies	Created PowerShell scripts (`run_part1.ps1`, `run_part2.ps1`) with proper error handling, progress tracking, and skip options
Data file dependencies	Pipeline fails if intermediate files missing	Added file existence checks and clear error messages at each pipeline step
Streamlit state management	Dashboard losing state on refresh	Used `@st.cache_resource` and `@st.cache_data` decorators to persist expensive computations
HTML report generation	Embedding matplotlib charts in standalone HTML	Learned Base64 encoding of PNG images to create self-contained HTML reports

10e. Key Learnings

Technical Learnings

1. **Hybrid Retrieval > Single Methods**: RRF fusion consistently outperformed both dense-only and sparse-only retrieval. The complementary nature of semantic (dense) and keyword (sparse) matching provides robustness.
2. **Metric Selection Matters**: ROUGE-L alone is insufficient – semantically equivalent answers with different wording score poorly. BERTScore captures semantic similarity but is computationally expensive. Using both provides a complete picture.
3. **Small LLMs Have Trade-offs**: TinyLlama (1.1B params) enables CPU-only deployment but sacrifices answer quality. For production systems, larger models or API-based LLMs (GPT-4, Claude) would be necessary.
4. **Prompt Engineering is Critical**: The exact wording of prompts significantly affects output quality. Explicit instructions ("use ONLY the provided context") and structured formats (ChatML) help constrain the model.
5. **Reproducibility Requires Planning**: Hash-based seeding (`hash("GROUP_122")`) ensures deterministic URL sampling. However, LLM generation introduces randomness – temperature=0.1 reduces but doesn't eliminate variation.

Process Learnings

1. **Iterative Development**: Started with simple implementations, then added complexity. For example, question generation evolved from pure LLM to LLM + fallback templates.
2. **Error Handling is Essential**: Production-quality code requires extensive try/except blocks, retries with backoff, and graceful degradation.
3. **Documentation During Development**: Writing CLAUDE.md alongside coding helped clarify implementation decisions and ensured nothing was forgotten.
4. **Visualization Aids Understanding**: The Streamlit dashboard made it much easier to understand metric distributions and identify failure patterns than raw CSV files.

10f. What I Would Do Differently

Aspect	Original Approach	Better Approach
Model choice	TinyLlama for everything	Use TinyLlama for dev/testing, larger model (Llama-2-7B) for final evaluation
Chunking strategy	Whole documents (200 words)	Smaller overlapping chunks (100 words, 50-word overlap) for better retrieval precision
Question generation	Random document sampling	Stratified sampling by domain to ensure balanced coverage
Evaluation set	100 questions	200+ questions for more statistically significant results

Aspect	Original Approach	Better Approach
Error analysis	Post-hoc categorization	Pre-defined failure taxonomy with automated classification

10g. Time Investment

Phase	Estimated Hours	Actual Hours	Notes
Environment setup	2	4	Dependency conflicts, model downloads
Part 1 implementation	8	12	Wikipedia API rate limits, FAISS debugging
Part 2 question gen	4	6	LLM output validation
Part 2 metrics	4	5	ROUGE/BERTScore library quirks
Part 2 evaluation	6	10	Ablation study, error analysis
Dashboard	4	6	Plotly learning curve, Streamlit caching
Documentation	4	5	README, CLAUDE.md
Total	**32**	**48**	~50% over initial estimate

10h. Skills Developed

- **Information Retrieval**: Dense (FAISS) + Sparse (BM25) retrieval, Reciprocal Rank Fusion
- **NLP Metrics**: MRR, ROUGE-L, BERTScore implementation and interpretation
- **LLM Deployment**: ctransformers, GGUF quantization, prompt engineering
- **Evaluation Design**: Ablation studies, LLM-as-Judge, error analysis taxonomy
- **Full-Stack ML**: End-to-end pipeline from data collection to interactive dashboard
